2000 jeep grand cherokee automatic transmission problems

Black Japanese Jeep on Astroid Open-Air Image from Fotolia. Transmission fluid must be checked every week to keep your Jeep Cherokee running properly; It adds lubrication to the transmission and allows your Jeep to change gears safely. Jeep Cherokees requires Automatic Transmission Fluid 4 (ATF 4) and mechanics recommend that the fluid be changed completely every 30,000 miles or as the vehicle's performance said. Make sure your Jeep Cherokee is ground level before adding or checking the liquid. Activate the parking brake on the vehicle. Make sure the car's at Park, too. Make sure your car is parked at ground level before proceeding, ensuring the stability of your vehicle and an accurate reading of the fluid level. Start the Jeep and leave it idle for about 15 minutes. The transmission fluid must be checked while the engine is at operating temperature so that the fluid level is accurate. Sitting the car gives the engine time to warm up. Open the hood and locate the buffer next to the car's transmission. This is on the back of the engine. The stick will contain a colored circle at the top, usually yellow or red. Remove the dipbaston and erase any transmission fluid. You need to clean this fluid so that when you reinstall the buffer, any fluid left on the stick will accurately reflect the level of transmission. Any fluid on your stick at this point is just excess and does not reflect a correct reading at the fluid level. Replace the cane. Wait three seconds to allow the fluid to fall into place, pull the dipstick and measure the fluid levels. Check if your transmission fluid reaches the "HOT" arrow. If it doesn't, add more transmission fluid. Place a funnel on the hose where the It is housed and slowly pour the transmission fluid, allowing it to flow into the fluid well. Repeat the process by adding more fluid and checking the dittick until you reach the "HOT" arrow. Problematic electrical problems on a Jeep Grand Cherokee Cherokee the use of a voltmeter with a scale ohm. A wiring diagram for the vehicle is a great help for harnessing problems and for computer related problems. All components that require a high amperage will have a relay between it and the switch. The higher the design or amperage needed to drive a component the larger the wire. It is not desirable to run a high amperage in a switch. All relays work as a switch. There are at least four terminals. A terminal will have power powered directly from the battery and the opposite terminal will go to the component. This circuit will be open until the relay is powered. The other two terminals are a switched power source of much less amperage and a ground. The switch operating the relay has power from the fuse block or from a bus bar which gives power to multiple circuits. When the switch is on, the energy passes through the relay to the ground, activating the relay as turning on a light. This connects the electrical terminal from the battery to the component by closing the circuit. This way, the relay has been remotely activated. All circuits are protected by a fuse or switch. Whenever there is a short, the amperage builds dramatically over what the cable can hold and it heats up and can light a fire. The higher the amperage needed to execute a component, the higher and lower the resistance of the wire. A lot of electrical diagnostics will be found a matter of common sense. All components need to get their power from a fused source and need good soil to work. If a component doesn't work, the first thing to do is make sure it has power and terrain. The computer on a car is the ground station to manage most of the components of the engine management system. The injectors, for example, receive power from the fuse lock whenever the key but they only work when the computer injector driver circuit surrounds them. The longer the computer makes available the injectors the more fuel is is in the engine. The injectors don't open far, for long. The same applies to most of the operational components such as inactive air control, variable valve timing, air injection pumps and so on. When it comes to sensors for input to the computer, the computer itself provides power at low voltage and receives a signal via pulse or differential voltage signals. Always start at the fuse and then the component for power and work at the fuse. Since the cover of each scenario would be a 200-page book, the most common problems will be listed below which can be easily executed. The yellow cable with a bold black stripe around it is the wire of the airbag actuator. It is very obvious and not a problem when performing electrical work. Don't probe this wire. If a yellow wire with a big bold black stripe is sounded, it will probably give birth to the air bag and will do physical damage. Enough has been said! Check the battery for 12.5 volts. If it has less, charge it or jump and if the car starts checking the battery to see if there are about 14.5 volts with the engine running. If not the alternator is bad. If it has the correct voltage, the battery is negative. If the battery was good, check the fuses and the starter relay. Pull the relay and check the power on a terminal with the button off. If there is no power supply, the problem is between the battery and the relay. If there is power to the relay, have a helper hold down the button in the initial position. There should be power in a second terminal now. If there is no power supply, the problem is in the ignition switch or with the safety system. If there is power supply, install the relay and check the main power in the large starter terminal. If there is no power supply, the wire from starter to battery is corroded or a battery terminal is not tight or good. If there is the helper is kept the key to start and check the small thread on the solenoid of the starter. If there is power, the appetizer is bad. If there is no power the wire from solenoid to relay is bad. A battery faster than you can load. It takes a lot more from the battery to start a car than it does to run it. A battery with a bad cell will lose much of its amperage and cause the alternator to continuously charge at a high rate of charge, which can overwhelm the heat and damage an alternator. The best way to check which battery is to hold the voltmeter through the battery terminals and watch the voltage when someone starts the car. If the voltage drops below 10.5 volts, the battery has a bad cell and needs replacement. An alternator doesn't usually fail all at once. Usually one of the diode packets gets bad first and reduces the amperage and the voltage it will turn off. With the car running, the voltage through the battery should be 14.5. Anything much lower and it will take a long time to charge the battery. Turn on the lights and the air conditioning. Tension should stay the same. If not, replace the alternator. To fix a check engine light, you will need an OBD II code scanner. The computer stores errors or failures in its memory and the scanner will access this memory and indicate what is not working. An OBD II scanner can be picked up at any auto parts shop and is not expensive. Connect the scanner in the connector under the driver's side dash. It's not hard to find and all cars have these. The key must be turned all the way with the engine off. Press the button on the scanner that says "Read." The computer will respond with a four-number code. Cross Reference The number with the code description sheet provided with the scanner and will explain what the problem is. Once you have replaced the part, press the Clear button and it will turn off the light. The brake light switch is on top of the arm Brake pedal. The button on the switch must be inserted with the brake pedal to the bottom. Otherwise, adjust it towards the pedal arm. Look for the hole in the arm where there was a rubber stop. If it is missing, put a bolt in the hole and the lights will turn off. If not the switch is bad. bad. bad.
